        auto f = *lower_bound(x);
        return MAX ? f(x) : -f(x);
    }
};

```

2.3 Digit dp

Counts the amount of numbers in $[l, r]$ such are divisible by k . (flag *nonzero* is for different lengths)
 It can be reduced to $dp(i, x, small)$, and has to be solved like $f(r) - f(l - 1)$

```

#define state [i][x][small][big][nonzero]
int dp(int i, int x, bool small, bool big, bool nonzero) {
    if (i == sz(r))
        return x % k == 0 && nonzero;
    int& ans = mem state;
    if (done state != timer) {
        done state = timer;
        ans = 0;
        int lo = small ? 0 : l[i] - '0';
        int hi = big ? 9 : r[i] - '0';
        for (y, lo, max(lo, hi) + 1) {
            bool small2 = small | (y > lo);
            bool big2 = big | (y < hi);
            bool nonzero2 = nonzero | (x > 0);
            ans += dp(i + 1, (x * 10 + y) % k, small2, big2, nonzero2);
        }
    }
    return ans;
}

```

2.4 Divide and conquer $\mathcal{O}(k \cdot n^2) \Rightarrow \mathcal{O}(k \cdot n \log n)$

Split the array of size n into k continuous groups. $k \leq n$
 $cost(a, c) + cost(b, d) \leq cost(a, d) + cost(b, c)$ with $a \leq b \leq c \leq d$

```

void solve(int cut, int l, int r, int optl, int optr) {
    if (r < l)
        return;
    int mid = (l + r) / 2;
    pair<lli, int> best = {INF, -1};
    for (p, optl, min(mid, optr) + 1)
        best = min(best, {dp[~cut & 1][p - 1] + cost(p, mid), p});
    dp[cut & 1][mid] = best.f;
    solve(cut, l, mid - 1, optl, best.s);
    solve(cut, mid + 1, r, best.s, optr);
}

for (i, 1, n + 1)
    dp[1][i] = cost(1, i);
for (cut, 2, k + 1)
    solve(cut, cut, n, cut, n);

```

2.5 Knapsack 01 $\mathcal{O}(n \cdot MaxW)$

```

for (i, 0, n)
    for (int x = MaxW; x >= w[i]; x--)
        umax(dp[x], dp[x - w[i]] + cost[i]);

```

2.6 Knuth $\mathcal{O}(n^3) \Rightarrow \mathcal{O}(n^2)$

$$dp[l][r] = \min_{l \leq k \leq r} \{dp[l][k] + dp[k][r]\} + cost(l, r)$$

```

lli dp[N][N];
int opt[N][N];

for (len, 1, n + 1)
    for (l, 0, n) {
        int r = l + len - 1;
        if (r > n - 1)
            break;
        if (len <= 2) {
            dp[l][r] = 0;
            opt[l][r] = 1;
            continue;
        }
        dp[l][r] = INF;
        for (k, opt[l][r - 1], opt[l + 1][r] + 1) {
            lli cur = dp[l][k] + dp[k][r] + cost(l, r);
            if (cur < dp[l][r]) {

<code>popcount(x)</code>	Amount of 1's in <i>x</i>
<code>clz(x)</code>	0's to the left of biggest bit
<code>ctz(x)</code>	0's to the right of smallest bit

11.2 Bitset

Bitset<Size>	
Operation	Function
<code>_Find_first()</code>	Least significant bit
<code>_Find_next(idx)</code>	First set bit after index <i>idx</i>
<code>any(), none(), all()</code>	Just what the expression says
<code>set(), reset(), flip()</code>	Just what the expression says x2
<code>to_string('.', 'A')</code>	Print 011010 like .AA.A.

11.3 Probability

Conditional

The event A happens and the event B has already happened

$$P(A|B) = \frac{P(A \cap B)}{P(B)}$$

If **independent** events

$$P(A|B) = P(A), P(B|A) = P(B)$$

Bayes theorem

$$P(A|B) = \frac{P(B|A) \cdot P(A)}{P(B)}$$

Binomial

$$B = \binom{n}{x} \cdot p^x \cdot (1-p)^{n-x}$$

n = number of trials

x = number of **success** from *n* trials

p = probability of **success** on a single trial

Geometric

Probability of success at the *n*th-event after failing the others

$$G = (1-p)^{n-1} \cdot p$$

n = number of trials

p = probability of *success* on a single trial

Poisson

$$Po = \frac{\lambda^k \cdot e^{-\lambda}}{k!}$$

λ = number of times an event is expected (occurs / time)

k = number of occurring events in the limited period of time

Example: The event happens 4 times per minute and we want *k* events to happen in 10 minutes, then $\lambda = 4 \cdot 10 = 40$

Expected value

$$E_x = \sum_{\forall x} x \cdot p(x)$$

11.4 Simplex

```
// maximize c^t x s.t. ax <= b, x >= 0
```

```
template <class T>
